DISEASE: Defects in SFXN1 are the cause of a transitory hypochromic, microcytic anemia characterized by a large number of siderocytes containing non-heme iron granules. The anemia begins at 12 dpc, is most intense at 15 dpc and is still severe at birth, but disappears by 2 weeks of age. Mutant adults are no longer anemic, but they have an impaired response to hemopoietic stress. Most homozygotes also have flexed tails and a belly spot. SIMILARITY: Belongs to the sideroflexin family.

III, Andrews N.C.;

"A mutation in a mitochondrial transmembrane protein is responsible for the pleiotropic hematological and skeletal phenotype of flexed-tail (f/f) mice.";

Genes Dev. 15:652-657(2001).

-!- FUNCTION: Potential iron transporter.

-!- SUBCELLULAR LOCATION: Mitochondrial (By similarity).

-!- TISSUE SPECIFICITY: Expressed in liver and brain.

-!- SIMILARITY: Belongs to the sideroflexin family.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  SEQUENCE OF 1-181 FROM N.A., AND TISSUE SPECIFICITY.

LOCATION: Mitochondrial (By similarity).
[FICITY: Largely restricted to kidney, brain and heart
Belongs to the sideroflexin family.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     TLEK 256

IN ADDITION IT MAY FUNCTION IN SOME ADHESION OR RECOGNITION
EVENTS AT THE CELL SURFACE.

IS SUBCULIT: DIMER (PROBABLE).

SUBCELLULAR LOCATION: TYPE I MEMBRANE PROTEIN. THE GCSFR-2 FORM,
WHICH LACKS THE TRANSMEMBRANE DOMAIN, MAY REPRESENT A SOLUBLE FORM,
OF THE RECEPTOR.

ALTERNATIVE PRODUCTS:
Event=Alternative splicing; Named isoforms=4;
Comment=Additional isoforms seem to exist. Experimental
confirmation may be lacking for some isoforms;
Name=1; Synonyms=GCSFR-1;
